

Project 3: Ants Vs. SomeBees

[ants.zip \(ants.zip\)](#)

*The bees are coming!
Create a better soldier
With inherit-ants.*

Introduction

In this project, you will create a tower defense (https://secure.wikimedia.org/wikipedia/en/wiki/Tower_defense) game called Ants Vs. SomeBees. As the ant queen, you populate your colony with the bravest ants you can muster. Your ants must protect their queen from the evil bees that invade your territory. Irritate the bees enough by throwing leaves at them, and they will be vanquished. Fail to pester the airborne intruders adequately, and your queen will succumb to the bees' wrath. This game is inspired by PopCap Games' Plants Vs. Zombies (<http://www.popcap.com/plants-vs-zombies-1>).

This project combines functional and object-oriented programming paradigms, focusing on the material from Chapter 2.5 (<http://composingprograms.com/pages/25-object-oriented-programming.html>) of Composing Programs. The project also involves understanding, extending, and testing a large program.

The ants.zip (ants.zip) archive contains several files, but all of your changes will be made to ants.py .

- ants.py : The game logic of Ants Vs. SomeBees
- ants_gui.py : The original GUI for Ants Vs. SomeBees
- gui.py : A new GUI for Ants Vs. SomeBees
- graphics.py : Utilities for displaying simple two-dimensional animations
- state.py : Abstraction for gamestate for gui.py
- utils.py : Some functions to facilitate the game interface
- ucb.py : Utility functions for CS 61A
- assets : A directory of images and files used by gui.py
- img : A directory of images used by ants_gui.py
- ok : The autograder
- proj3.ok : The ok configuration file
- tests : A directory of tests used by ok
- mytests.rst : A space for you to add your custom tests; see section on adding your own tests

Ok includes a collaboration environment so that you can work on the project with your partner in a browser (like Google Docs). More information is available on the demo video (<https://youtu.be/CsL1l2Pb-EM>).

```
python3 ok --collab
```

Logistics

This is a 11-day project. You may work with one other partner. You should not share your code with students who are not your partner or copy from anyone else's solutions. In the end, you will submit one project for both partners.

Remember that you can earn an additional bonus point by submitting the project at least 24 hours before the deadline.

The project is worth 27 points. 25 points are assigned for correctness, and 2 points for the overall composition (../../articles/composition.html) of your program.

You will turn in the following files:

- ants.py

You do not need to modify or turn in any other files to complete the project. To submit the project, run the following command:

```
python3 ok --submit
```

You will be able to view your submissions on the Ok dashboard (<http://ok.cs61a.org>).

For the functions that we ask you to complete, there may be some initial code that we provide. If you would rather not use that code, feel free to delete it and start from scratch. You may also add new function definitions as you see fit.

However, please do **not** modify any other functions. Doing so may result in your code failing our autograder tests. Also, please do not change any function signatures (names, argument order, or number of arguments).

Testing

Throughout this project, you should be testing the correctness of your code. It is good practice to test often, so that it is easy to isolate any problems. However, you should not be testing *too* often, to allow yourself time to think through problems.

We have provided an **autograder** called `ok` to help you with testing your code and tracking your progress. The first time you run the autograder, you will be asked to **log in with your Ok account using your web browser**. Please do so. Each time you run `ok`, it will back up your work and progress on our servers.

The primary purpose of `ok` is to test your implementations, but there are two things you should be aware of.

First, some of the test cases are *locked*. To unlock tests, run the following command from your terminal:

```
python3 ok -u
```

This command will start an interactive prompt that looks like:

```
=====
Assignment: Ants Vs. SomeBees
Ok, version ...
=====
```

```
~~~~~
Unlocking tests
```

At each "? ", type what you would expect the output to be.

Type exit() to quit

```
-----
Question 0 > Suite 1 > Case 1
(cases remaining: 1)
```

```
>>> Code here
```

```
?
```

At the ?, you can type what you expect the output to be. If you are correct, then this test case will be available the next time you run the autograder.

The idea is to understand *conceptually* what your program should do first, before you start writing any code.

Once you have unlocked some tests and written some code, you can check the correctness of your program using the tests that you have unlocked:

```
python3 ok
```

Most of the time, you will want to focus on a particular question. Use the -q option as directed in the problems below.

We recommend that you submit **after you finish each problem**. Only your last submission will be graded. It is also useful for us to have more backups of your code in case you run into a submission issue.

The tests folder is used to store autograder tests, so **do not modify it**. You may lose all your unlocking progress if you do. If you need to get a fresh copy, you can download the zip archive (ants.zip) and copy it over, but you will need to start unlocking from scratch.

If you do not want us to record a backup of your work or information about your progress, use the --local option when invoking ok . With this option, no information will be sent to our course servers.

Ok has the ability to run a single test case! e.g. `python3 ok -q 01 --suite 1 --case 2`. Try it out if you ever get stuck on a specific case.

Core Concepts

A game of Ants Vs. SomeBees consists of a series of turns. In each turn, new bees may enter the ant colony. Then, new ants are placed. Finally, all insects (ants, then bees) take individual actions: bees sting ants, and ants throw leaves at bees. The game ends either when a bee reaches the ant queen (you lose), or the entire bee flotilla has been vanquished (you win).

The Colony. The colony consists of several places that are chained together. The exit of each Place leads to another Place .

Placing Ants. There are two constraints that limit ant production. Placing an ant uses up some amount of the colony's food, a different amount for each type of ant. Also, only one ant can occupy each Place .

Bees. When it is time to act, a bee either moves to the exit of its current Place if no ant blocks its path, or stings an ant that blocks its path.

Ants. Each type of ant takes a different action and requires a different amount of food to place. The two most basic ant types are the `HarvesterAnt` , which adds one food to the colony during each turn, and the `ThrowerAnt` , which throws a leaf at a bee each turn.

The Code

Most concepts in the game have a corresponding class that encapsulates the logic for that concept. For instance, a Place in the colony holds insects and connects to other places. A Bee stings ants and advances through exits.

The game can be run in two modes: as a text-based game or using a graphical user interface (GUI). The game logic is the same in either case, but the GUI enforces a turn time limit that makes playing the game more exciting. The text-based interface is provided for debugging and development.

The files are separated according to these two modes. `ants.py` knows nothing of graphics or turn time limits.

To start a text-based game, run

```
python3 ants.py
```

To start a graphical game, run

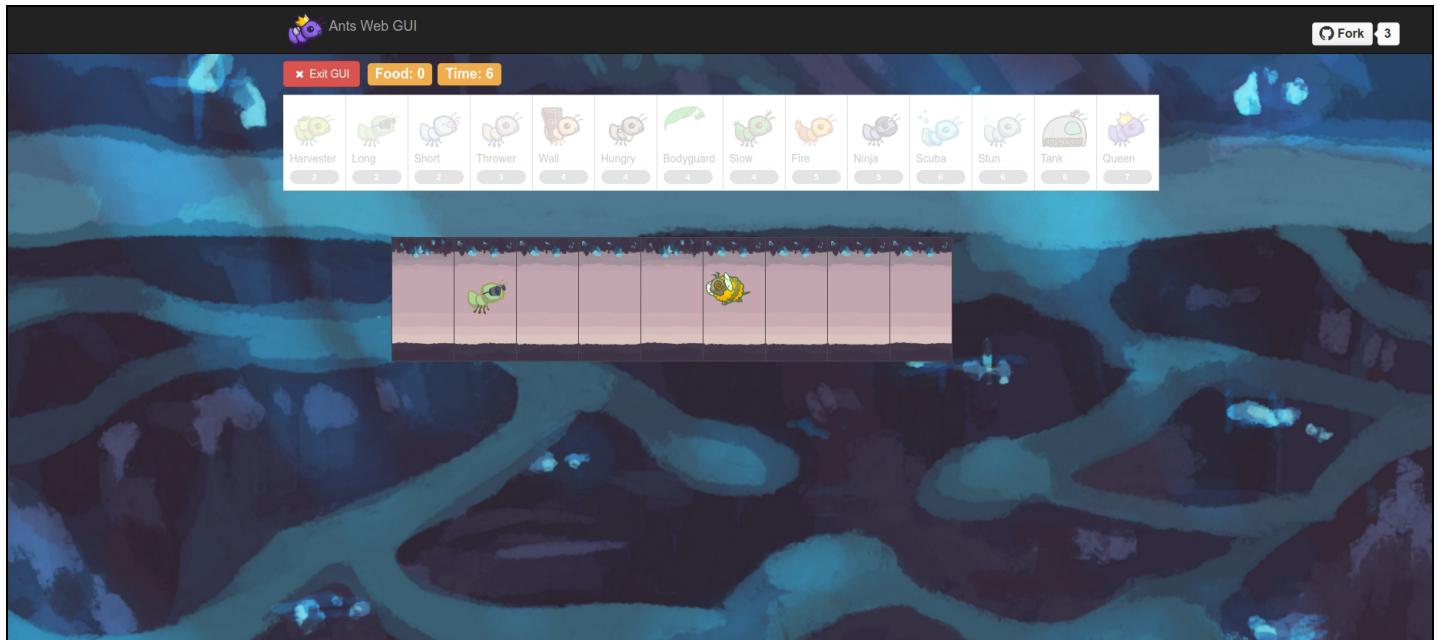

```
python3 gui.py
```

To start an older version of the graphics, run

```
python3 ants_gui.py
```

When you start the graphical version, a new window should appear:

Current graphics:

In the starter implementation, you have unlimited food and your ants only throw leaves at bees in their current Place. Try playing the game anyway! You'll need to place a lot of ThrowerAnts (the second type) in order to keep the bees from reaching your queen.

The game has several options that you will use throughout the project, which you can view with `python3 ants.py --help`.

```
usage: ants.py [-h] [-d DIFFICULTY] [-w] [--food FOOD]
```

Play Ants vs. SomeBees

optional arguments:

- h, --help show **this** help message and exit
- d DIFFICULTY sets difficulty **of** game (test/easy/medium/hard/insane)
- w, --water loads a full layout **with** water
- food FOOD number **of** food to start **with** when testing

Your own test cases

Adding your own tests is **entirely optional**, and you will not submit your `mytests.rst` file.

We highly recommend that you add your own tests as you work through the project. It's a really helpful way to speed up the debugging process and improve your understanding of the code.

The course staff has also made an instructional video (<https://youtu.be/o1TD0K1xWXs>) summarizing the information below.

Adding tests

The screenshot shows a terminal window displaying the contents of a file named `mytests.rst`. The file is an IDEAL TEST FILE. It contains several sections: a `Suite alpha` section with a shared environment, a `Case zeus` section with a doctest example, a `Case 1` section, and a `Suite lists` section. Annotations with arrows point to specific parts of the code:

- An arrow from the text "Suites and Cases Supported" points to the `Suite alpha` label.
- An arrow from the text "Labels can be semantic (+alphanumeric)" points to the `Case 1` label.
- An arrow from the text "Shared area - Common env across cases in suite" points to the `>>> why = 'not'` line.
- An arrow from the text "Standard Python doctest format" points to the doctest example in the `Case zeus` section.

```
mytests.rst
1 This file is for student-created tests. Remember to import the python file(s)
2 you wish to test, along with any other modules you may need.
3 Run tests with "python3 ok -t"
4
5 IDEAL TEST FILE
6
7
8 Suite alpha
9
10    >>> why = 'not'
11
12 Case zeus
13
14    >>> hmmm(why)
15    '01101000 01101101 01101101 01101101'
16    >>> inf_loop(10)
17    'ok'
18
19 Case 1
20
21    >>> cube(0)
22    0
23    >>> neverlucky()
24    7
25
26 Suite lists
27
28    >>> master = [1, 2, 3]
29    >>> more = [4, 5, 6]
```

Adding tests is easy. Directly edit the `mytests.rst` file included with the Ants project. We provide a sample structure to start from, but the test format is actually quite flexible. Here are some simple rules to follow:

- Follow standard Python doctest format. This is what we mostly use for the Ok tests, so feel free to use those as examples.
- For the most part, you may use whitespace as you'd like, but we recommend keeping it organized for your own sake.
- Generally, smaller, simpler tests will be more useful than larger, more complex tests.

You may also find our debugging guide ([/~cs61a/fa17/articles/debugging.html#debugging-process](#)) helpful. If you're stuck on a particularly tricky `ok` test case, a good first step would be to break it up into small parts and test them out yourself in `mytests.rst`.

Running tests

To run all your tests in `mytests.rst` with verbose results:

```
python3 ok -t -v
```

If you put your tests in a different file or split your tests up into multiple files:

```
python3 ok -t your_new_filename.rst
```

To run just the tests from suite 1 case 1 in `mytests.rst`:

```
python3 ok -t --suite 1 --case 1
```

You might have noticed that there's a "test coverage" percentage for your tests (note that coverage statistics are only returned when running all tests). This is a measure of your test's code coverage (https://en.wikipedia.org/wiki/Code_coverage). If you're interested, you can find more information in our reference guide ([/~cs61a/fa17/articles/using-ok.html#running-your-own-tests](#)).

Phase 1

Problem 0 (0 pt)

Answer the following questions with your partner after you have read the *entire* `ants.py` file. If you cannot answer these questions, read the file again or ask a question in the Question 0 thread on Piazza.

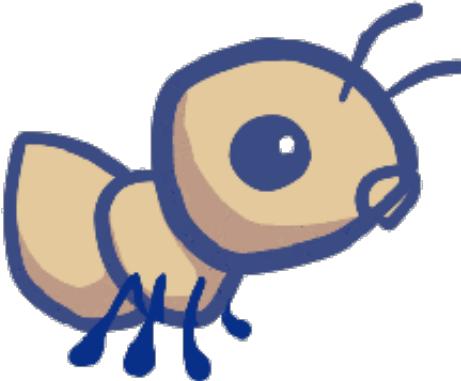

1. What is the significance of an insect's `armor` attribute? What happens when `armor` reaches 0?
2. What are all of the attributes of the `Ant` class?
3. Is the `armor` attribute of the `Ant` class an instance attribute or class attribute?
4. Is the `damage` attribute of an `Ant` subclass (such as `ThrowerAnt`) an instance attribute or class attribute?
5. Which class do both `Ant` and `Bee` inherit from?
6. What attribute(s) do `Ant` and `Bee` inherit from their base class?

You can test your understanding by running

```
python3 ok -q 00 -u
```

Problem 1 (2 pt)

Add food costs and implement harvesters. Currently, there is no cost for deploying any type of `Ant`, and so there is no challenge to the game. You'll notice that `Ant` starts out with a base `food_cost` of zero. Override this value in each of the subclasses listed below with the correct costs.

Class	Food Cost	Armor
 HarvesterAnt	2	1
 ThrowerAnt	3	1

Now there's no way to gather more food! To fix this issue, implement the `HarvesterAnt` class. A `HarvesterAnt` is a type of `Ant` that adds one food to the `colony.food` total as its action.

Test your implementation before moving on:

```
python3 ok -q 01 -u
python3 ok -q 01
```

Remember: Ok now has the ability to run a single test case! e.g. `python3 ok -q 01 -suite 1 --case 2`. Try it out if you ever get stuck on a specific case.

Try playing the game again (`python3 gui.py`). Once you have placed a `HarvesterAnt`, you should accumulate food each turn. Vanquishing the bees using the default game setup is now possible.

Problem 2 (2 pt)

Add code to the `Place` constructor that tracks entrances. Right now, a `Place` keeps track only of its `exit`. We would like a `Place` to keep track of its entrance as well. A `Place` needs to track only one entrance .

However, simply passing an entrance to a `Place` constructor will be problematic; we would need to have both the exit and the entrance before creating a `Place`! (It's a chicken or the egg (https://secure.wikimedia.org/wikipedia/en/wiki/Chicken_or_the_egg) problem.) To get around this problem, we will keep track of entrances in the following way instead. The `Place` constructor should specify that:

- A newly created `Place` always starts with its entrance as `None`.
- If the `Place` has an `exit`, then the `exit`'s entrance is set to that `Place`.

Test your implementation before moving on:

```
python3 ok -q 02 -u  
python3 ok -q 02
```

Phase 2: Water and Fire

Problem 3 (1 pt)

Let's add water to the colony! Currently there are only two types of places, the `Hive` and a basic `Place`. To make things more interesting, we're going to create a new type of `Place` called `Water`.

Only an ant that is `watersafe` can be deployed to a `Water` place. In order to determine whether an `Insect` is `watersafe`, add a new attribute to the `Insect` class named `watersafe` that is `False` by default. Since bees can fly, make their `watersafe` attribute `True`, overriding the default.

Now, implement the `add_insect` method for `Water`. First call `Place.add_insect` to add the insect, regardless of whether it is `watersafe`. Then, if the insect is not `watersafe`, reduce the insect's armor to 0 by invoking `reduce_armor`. *Do not copy and paste code.* Instead, use methods that have already been defined and make use of inheritance to reuse the functionality of the `Place` class.

Test your implementation before moving on:

```
python3 ok -q 03 -u  
python3 ok -q 03
```

Once you've finished this problem, play a game that includes water. To access the `wet_layout` which includes water, add the `--water` option (or `-w` for short) when you start the game.

```
python3 gui.py --water
```

Problem 4 (2 pt)

Implement the `FireAnt`. A `FireAnt` has a special `reduce_armor` method: when the `FireAnt`'s armor reaches zero or lower, it will reduce the armor of *all* Bees in the same Place as the `FireAnt` by its damage attribute (defaults to 3).

Class	Food Cost	Armor
 FireAnt	5	1

Hint: Damaging a bee may cause it to be removed from its place. If you iterate over a list, but change the contents of that list at the same time, you may not visit all the elements. As the Python tutorial (<https://docs.python.org/3/tutorial/controlflow.html#for-statements>) suggests, "If you need to modify the sequence you are iterating over while inside the loop (for example to duplicate selected items), it is recommended that you first make a copy." You can copy a list by calling the `list` constructor or slicing the list from the beginning to the end.

Once you've finished implementing the `FireAnt`, give it a class attribute implemented with the value `True`. This attribute tells the game that you've added a new type of `Ant`.

Test your implementation before moving on:

```
python3 ok -q 04 -u  
python3 ok -q 04
```

After implementing `FireAnt`, be sure to test your program by playing a game or two! A `FireAnt` should destroy all co-located Bees when it is stung. To start a game with ten food (for easy testing):

```
python3 gui.py --food 10
```

Phase 3: Extended Range

Problem 5 (1 pt)

Implement the `nearest_bee` method for the `ThrowerAnt` class. In order for a `ThrowerAnt` to attack, it must know which bee it should hit. The provided implementation will only hit bees in the same `Place`. Your job is to fix it so that a `ThrowerAnt` will `throw_at` the nearest bee in front of it that is not still in the `Hive`.

The `nearest_bee` method returns a random Bee from the nearest place that contains bees. Places are inspected in order by following their entrance attributes.

- Start from the current Place of the ThrowerAnt .
- For each place, return a random bee if there is any, or consider the next place that is stored as the current place's entrance .
- If there is no bee to attack (or none within range), return None .

Hint: The `random_or_none` function provided in `ants.py` returns a random element of a sequence.

Test your implementation before moving on:

```
python3 ok -q 05 -u  
python3 ok -q 05
```

After implementing `nearest_bee`, a ThrowerAnt should be able to `throw_at` a Bee in front of it that is not still in the Hive . Make sure that your ants do the right thing! To start a game with ten food (for easy testing):

```
python3 gui.py --food 10
```

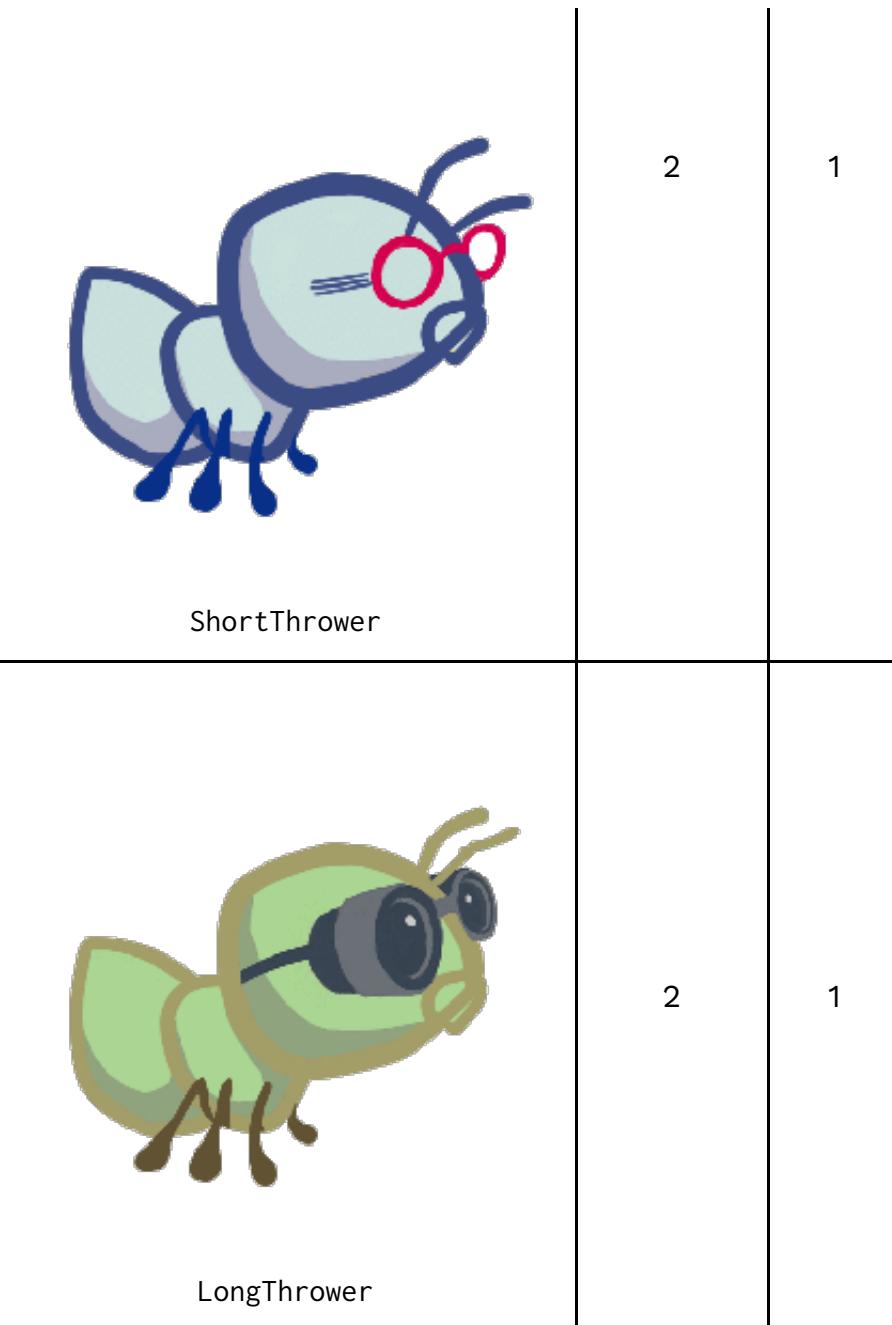

Problem 6 (2 pt)

Now that the ThrowerAnt has been completed, implement two subclasses of ThrowerAnt .

- The LongThrower can only `throw_at` a Bee that is found after following at least 5 entrance transitions. So the LongThrower can't hit Bees that are in the same Place as it or the first 4 Places in front of it. If there are two Bees , one too close to the LongThrower and the other within its range, the LongThrower should throw past the closer Bee , instead targeting the farther one, which is within its range.
- The ShortThrower can only `throw_at` a Bee that is found after following at most 3 entrance transitions. So the ShortThrower can only hit Bees in the same Place as it and 3 Places in front of it.

Neither of these specialized throwers can `throw_at` a Bee that is exactly 4 Places away. Placing a single one of these (and no other ants) should never win a default game.

Class	Food Cost	Armor

A good way to approach the implementation to `ShortThrower` and `LongThrower` is to have it inherit the `nearest_bee` method from the base `ThrowerAnt` class. The logic of choosing which bee a thrower ant will attack is essentially the same, except the `ShortThrower` and `LongThrower` ants have maximum and minimum ranges, respectively.

To implement these behaviors, you may need to modify the `nearest_bee` method to reference `min_range` and `max_range` attributes, and only return a bee that is in range.

The `ThrowerAnt` has no minimum or maximum range, so make sure that its `min_range` and `max_range` attributes should reflect that. Then, implement the subclasses `LongThrower` and `ShortThrower` with appropriately constrained ranges and correct food costs.

Don't forget to set the implemented class attribute of `LongThrower` and `ShortThrower` to `True`.

Test your implementation before moving on:

```
python3 ok -q 06 -u  
python3 ok -q 06
```

Phase 4: Seen and Unseen

With your Phase 2 ants, try `python3 ants_gui.py -d easy` to play against a full swarm of bees in a multi-tunnel layout and try `-d normal`, `-d hard`, or `-d insane` if you want a real challenge! If the bees are too numerous to vanquish, you might need to create some new ants.

Problem 7 (1 pt)

We are going to add some protection to our glorious `AntColony` by implementing the `WallAnt`, which is an ant that does nothing each turn. A `WallAnt` is useful because it has a large armor value.

Class	Food Cost	Armor
 WallAnt	4	4

Unlike with previous ants, we have not provided you with a class header. Implement the `WallAnt` class from scratch. Give it a class attribute `name` with the value 'Wall' (so that the graphics work) and a class attribute `implemented` with the value `True` (so that you can use it in a game).

Test your implementation before moving on:

```
python3 ok -q 07 -u  
python3 ok -q 07
```

Problem 8 (2 pt)

Implement the `NinjaAnt`, which damages all `Bee`s that pass by, but can never be stung.

Class	Food Cost	Armor
 NinjaAnt	5	1

A NinjaAnt does not block the path of a Bee that flies by. To implement this behavior, first modify the Ant class to include a new class attribute blocks_path that is True by default. Set the value of blocks_path to False in the NinjaAnt class.

Second, modify the Bee's method blocked to return False if either there is no Ant in the Bee's place or if there is an Ant, but its blocks_path attribute is False. Now Bee's will just fly past NinjaAnt's.

Finally, we want to make the NinjaAnt damage all Bee's that fly past. Implement the action method in NinjaAnt to reduce the armor of all Bee's in the same place as the NinjaAnt by its damage attribute. Similar to the FireAnt, you must iterate over a list of bees that may change.

Test your implementation before moving on:

```
python3 ok -q 08 -u
python3 ok -q 08
```

For a challenge, try to win a game using only HarvesterAnt and NinjaAnt.

Phase 5: By Land and Sea

Problem 9 (1 pt)

Currently there are no ants that can be placed on Water. Implement the ScubaThrower, which is a subclass of ThrowerAnt that is more costly and watersafe, but otherwise identical to its base class. A ScubaThrower should not lose its armor when placed in Water.

Class	Food Cost	Armor
 ScubaThrower	6	1

Unlike with previous ants, we have not provided you with a class header. Implement the ScubaThrower class from scratch. Give it a class attribute name with the value 'Scuba' (so that the graphics work) and a class attribute implemented with the value True (so that you can use it in a game).

Test your implementation before moving on:

```
python3 ok -q 09 -u
```

```
python3 ok -q 09
```

Problem 10 (2 pt)

We will now implement the new offensive unit called the `HungryAnt`, which will select a random Bee from its place and eat it whole. After eating a Bee, it must spend 3 turns digesting before eating again.

Class	Food Cost	Armor
 HungryAnt	4	1

Give `HungryAnt` a `time_to_digest` class attribute that holds the number of turns that it takes a `HungryAnt` to digest (default to 3). Also, give each `HungryAnt` an instance attribute `digesting` that counts the number of turns it has left to digest (default is 0, since it hasn't eaten anything at the beginning).

Implement the `action` method of the `HungryAnt` to check if it's digesting; if so, decrement its `digesting` counter. Otherwise, eat a random Bee in its place by reducing the Bee's armor to 0 and restart the digesting timer.

Test your implementation before moving on:

```
python3 ok -q 10 -u
```

```
python3 ok -q 10
```

Phase 6

Problem 11 (4 pt)

Right now, our ants are quite frail. We'd like to provide a way to help them last longer against the onslaught of the bees. Enter the `BodyguardAnt`.

Class	Food Cost	Armor

4

2

BodyguardAnt

A BodyguardAnt differs from a normal ant because it is a container ; it can contain another ant and protect it, all in one Place . When a Bee stings the ant in a Place where one ant contains another, only the container is damaged. The ant inside the container can still perform its original action. If the container perishes, the contained ant still remains in the place (and can then be damaged).

Each BodyguardAnt has an instance attribute `ant` that stores the ant it contains. It initially starts off as `None` , to indicate that no ant is being protected. The `contain_ant` method takes an `Ant` argument and sets the bodyguard's `ant` instance attribute; you will need to implement this as well as the BodyguardAnt 's `action` method.

In addition, you will need to make modifications throughout your program so that a container and its contained ant can both occupy the place at the same time (a maximum of two ants per place), but only if exactly one is a container .

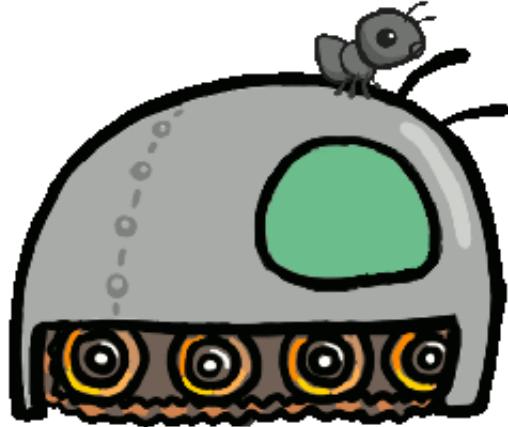

1. Add an `Ant.container` class attribute that indicates whether a subclass of `Ant` is a container. For all `Ant` instances, except for `BodyguardAnt` instances, `container` should be `False` . The `BodyguardAnt.container` attribute should be `True` .
2. Add a method `Ant.can_contain` that takes the other ant as an argument and returns `True` when:
 - o This ant is a container.
 - o This ant does not already contain another ant.
 - o The other ant is not a container.
3. Modify `Place.add_insect` to allow a container and a non-container ant to occupy the same place according to the following rules:
 - o If the ant currently occupying a Place can contain the insect (an `Ant`) passed to `add_insect` , then it does.
 - o If the insect (an `Ant`) passed to `add_insect` can contain the ant currently occupying a Place , then it does. Also, set the Place 's `ant` to be the container insect.
 - o If neither Ant can contain the other, raise the same `AssertionError` as before (the one already present in the starter code).

Test your implementation before moving on:

```
python3 ok -q 11 -u  
python3 ok -q 11
```

Problem 12 (1 pt)

The `BodyguardAnt` provides great defense, but they say the best defense is a good offense. The `TankAnt` is a container that protects an ant in its place and also deals 1 damage to all bees in its place each turn.

Class	Food Cost	Armor
 TankAnt	6	2

You should not need to modify any code outside of the `TankAnt` class. If you find yourself needing to make changes elsewhere, look for a way to write your code for the previous question such that it applies not just to `BodyguardAnt` and `TankAnt` objects, but to container ants in general.

Test your implementation before moving on:

```
python3 ok -q 12 -u  
python3 ok -q 12
```

Problem 13 (4 pt)

Implement the `QueenAnt`. The queen is a waterproof `ScubaThrower` that inspires her fellow ants through her bravery. The `QueenAnt` doubles the damage of all the ants behind her each time she performs an action. Once an ant's damage has been doubled, it is *not* doubled again for subsequent turns.

Class	Food Cost	Armor

	7	1
QueenAnt		

However, with great power comes great responsibility. The QueenAnt is governed by three special rules:

1. If the queen ever has its armor reduced to 0, the bees win. The bees also still win if any bee reaches the end of a tunnel.
2. There can be only one true queen. Any queen instantiated beyond the first one is an impostor, and should have its armor reduced to 0 upon taking its first action, without doubling any ant's damage or throwing anything. If an impostor dies, the game should still continue as normal.
3. The true (first) queen cannot be removed. Attempts to remove the queen should have no effect (but should not cause an error). You will need to modify the `remove_insect` method of Place to enforce this condition.

Some suggestions:

- Call `bees_win()` to signal to the simulator that the game is over.
- You can find each Place in a tunnel behind the QueenAnt by starting at the ant's `place.exit` and then repeatedly following its `exit`.
- To detect whether a Place is at the end of a tunnel, check whether its `exit` is `None`.
- To make sure that you don't double the damage of the same ant twice, maintain a list of all the ants that have been doubled.
- You may find the `isinstance` function useful for checking if something is an instance of an object. For example:

```
>>> a = Foo()
>>> isinstance(a, Foo)
True
```

Test your implementation before moving on:

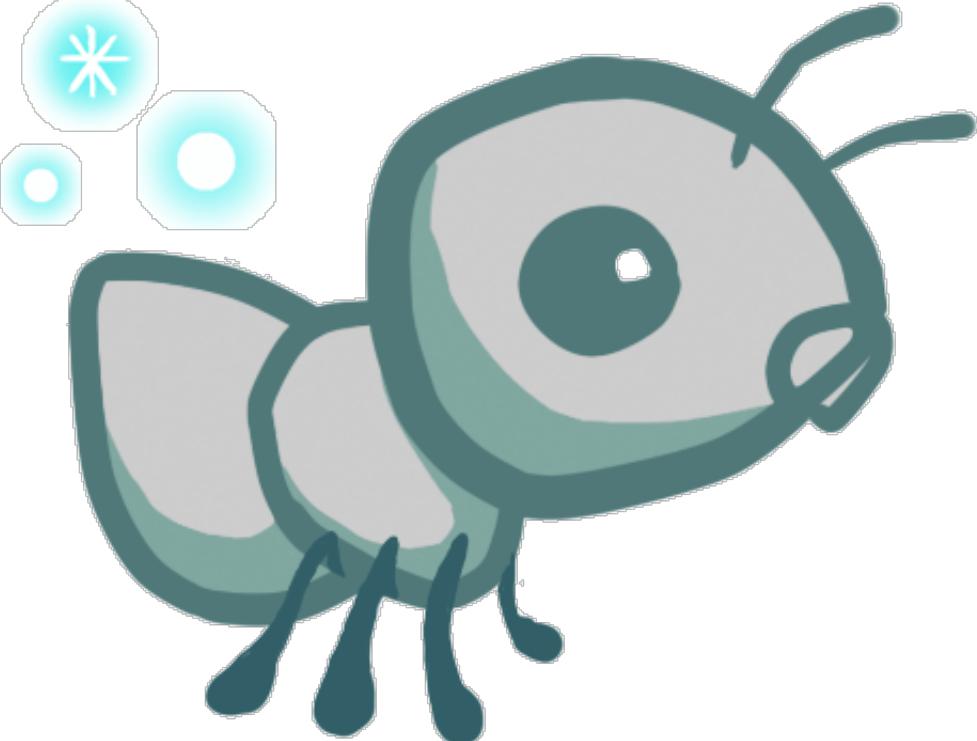

```
python3 ok -q 13 -u
python3 ok -q 13
```

Extra Credit (2 pt)

Implement two final thrower ants that do zero damage, but instead produce a temporary "effect" on the `action` method of a Bee instance that they `throw_at`. This effect is an alternative action that lasts for a certain number of `.action(colony)` calls, after which the Bee's action reverts to its original behavior.

We will be implementing two new ants that subclass ThrowerAnt .

- SlowThrower applies a slow effect for 3 turns.
- StunThrower applies a stun effect for 1 turn.

Class	Food Cost	Armor
 SlowThrower	4	1
 StunThrower	6	1

In order to complete the implementations of these two ants, you will need to set their class attributes appropriately and implement the following three functions:

1. `make_slow` is an effect that takes an `action` method and returns a new `action` method that performs the original action on turns where `colony.time` is even and does nothing on other turns.
2. `make_stun` is an effect that takes an `action` method and returns a new `action` method that does nothing.
3. `apply_effect` takes an effect (either `make_slow` or `make_stun`), a `Bee`, and a `duration`. It uses the effect on the `Bee`'s `.action` method to produce a new `action` method, and then arranges to have the new method become the bee's `action` method for the next `duration` times that `.action` is called, after which the previous `.action` method is restored.

You can run some provided tests, but they are not exhaustive:

```
python3 ok -q EC -u
python3 ok -q EC
```

Make sure to test your code! Your code should be able to apply multiple effects on a target; each new effect applies to the current (possibly affected) action method of the bee.

You are now done with the project! If you haven't yet, you should try playing the game! There are two GUIs that you can use. The first is a new browser GUI that has fancy graphics and animations. The command to run it is:

```
python3 gui.py [-h] [-d DIFFICULTY] [-w] [--food FOOD]
```

The second is an older, but tried-and-true interface that we have been using over the past few years. The command to run it is:

```
python3 ants_gui.py [-h] [-d DIFFICULTY] [-w] [--food FOOD]
```

Acknowledgments: Tom Magrino and Eric Tzeng developed this project with John DeNero. Jessica Wan contributed the original artwork. Joy Jeng and Mark Miyashita invented the queen ant. Many others have contributed to the project as well!

Colin Schoen developed the new browser GUI. The beautiful new artwork was drawn by the efforts of Alana Tran, Andrew Huang, Emilee Chen, Jessie Salas, Jingyi Li, Katherine Xu, Meena Vempaty, Michelle Chang, and Ryan Davis.
